

ABACÁ (MANILA HEMP) IN THE PHILIPPINES

(Musa textilis.)

By M. M. SALEEBY, Chief, Fiber Division, Bureau of Agriculture

Introduction.—Abacá is not only the most important fiber, but also the most important export product, of the Philippines. For a number of years this fiber comprised approximately two-thirds of the total ex-The recent increase in the port trade of the Islands. production of copra and sugar has reduced in a measure its relative importance, but it still remains our leading export product.

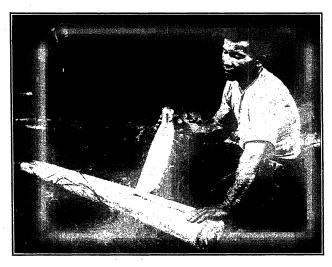

Abacá is the premier cordage fiber of the world. It is a structural (hard) fiber obtained from the outer layers of the overlapping leaf sheaths which form the stalks of the abacá plant. It is very light, strong, and durable. When properly extracted and dried, it is also of a white, lustrous color. One particular feature of the abacá fiber which emphasizes its superiority over all other fibers of its class is its great strength and its resistance to the action of water, hence its particular adaptability for marine ropes.

In the commercial world this fiber is known as "manila hemp" or "manila." It is often called "hemp," especially locally by the English-speaking community, but this term is both incorrect and misleading, and its use should be discontinued in favor of the Spanish-Filipino term "abacá."

History of the industry.-The first authentic account of the use of either abacá or banana fiber in the Philippines is that given by an Englishman, Dampier, who lived in Mindanao in 1686. This writer describes the "banana textoria," both as an edible

and as a fiber-producing plant.¹ One of the companions of Magellan, Antonio Pigafetta, prepared a description of the plants of the Philippines, but in this paper no mention is made of abacá. The fiber was first exported from the Islands about the beginning of the last century, but the export did not become important until about 1850. In 1820 a sample of abacá was brought to Salem, Mass., by John

Stripping abacá (manila hemp) first process, Albay.

White, a lieutenant in the United States Navy. From 1824 to 1827 the fiber began to be used quite extensively in Salem and Boston.²

The production of abacá for export did not commence until 1818, when 41 tons were exported. Until 1830 the exports ranged from 100 to 500 tons; but in 1840 they increased to 8,502, or an increase of 8,000 tons in about ten years. During the ten years from 1840 to 1850, the exports remained prac-

² From Bureau of Agriculture Bulletin No. 12, page 10, Manila, P. I.

tically stationary, amounting to 8,561 tons in the latter year. The decade from 1850 to 1860 shows an increase from 8,561 tons to 30,388; while that from 1860 to 1870 shows an increase of from 30,388 to 31,426, or about 1,100 tons only. From 1870 until 1900, the exports increased from 31,426 to 89,438 tons, with an average increase of about 20,000 tons during each decade.

The quantity and value of the exports of abacá from the Philippines since the fiscal year ending June 30, 1900, are as follows:

Fiscal year ending June 30-	All countries.		Percent- age of	Average local
	Quantity.	Value.	total exports.	value
1	Met.tonsa	and the second second second second		
1900	76, 709	\$11, 393, 883	52.6	\$148.53

[Values in U. S. currency.]

^a One metric ton equals 2,204.62 avoirdupois pounds.

During the whole history of the abacá industry, the fiber has been identified with the Philippines. This is due to the fact that the introduction of the abacá plant into other tropical countries, in both the Eastern and the Western Hemispheres, has not resulted in any considerable degree of success, and the fiber is still, as it always has been, distinctly a Philippine product.

Distribution.—Abacá is distributed throughout the greater part of the Philippine Archipelago. The provinces and islands which are most favorable for the growth of the plant and where the greater part of the commercial fiber is produced are the following: Southern Luzon, comprising the Provinces of Ambos Camarines, Albay, and Sorsogon; Leyte, chiefly the northeastern and southern parts; Samar, chiefly the northern and southeastern parts; and Mindanao, comprising the Provinces of Moro, Misamis, Surigao, and Agusan. The plant is also cultivated to some extent in the Islands of Negros, Cebu, Mindoro, Panav, and Marinduque. The most northern limit of the cultivation of abacá is central southern Luzon. comprising the Provinces of Cavite, Laguna, and Batangas.

During the fiscal year ending June 30, 1913, the total area under cultivation in abacá throughout the Philippine Islands was about 909,849 acres, distributed among the provinces as follows: Albay, 219,155; Ambos Camarines, 171,018; Sorsogon, 157.815; Levte, 110.948; Samar, 68.143; Moro, 48,254; Misamis, 35,167; Surigao, 14,376; and the remaining provinces, 84,973.

Climate and soil.-The structure of the abacá plant and its habits of growth are such that a large and constant supply of moisture is required. The most important abacá provinces have, as a rule, a heavy and evenly distributed rainfall. The actual amount of rainfall required by the abacá plant is not very large, but it is essential that it be evenly distributed throughout the year. In districts having a long and pronounced dry season, irrespective of the annual amount of rainfall, the cultivation of abacá can not be successfully carried on unless water is available for irrigation.

The abacá plant requires a warm climate, and for this reason its successful cultivation can be accomplished only in tropical countries and below an ele-

vation of 1,000 meters (3,280 feet.) Cold climates are detrimental to the plant, both in regard to the extent of its growth and the development of its fiber. Extreme heat, on the other hand, appears to affect

Abacá (manila hemp), Sinaba and Tangongon varieties, Davao, Mindanao.

the plant unfavorably, probably because it causes excessive and rapid evaporation of moisture both from the leaves and the soil, especially during the driest period of the year.

ĹĹĹĹ

The abacá plant with its heavy broad leaves is very often seriously injured by strong winds. It is, therefore, always desirable to select localities which are naturally protected from such winds, especially in all provinces lying within the typhoon belt. If natural barriers are not available, windbreaks must be planted along the exposed side or sides and also at intervals among the plants.

Next in importance to favorable climatic conditions is the selection of a suitable soil. The suitability of any particular type of soil of necessity depends, on the one hand, on the climatic conditions, and on the other, on the location. For instance, in a certain location where the land is low and where a heavy rainfall occurs, a certain soil would become oversaturated, while the same type of soil, if the land were higher and the rainfall less abundant, might be sufficiently well drained.

Throughout the important abacá districts the plantations are situated on the lower slopes of volcanoes or other mountains. The soils in such locations are, as a rule, deep, fertile, and well drained. Besides being well drained, the soil should be of lasting fertility, as abacá is grown on the same land for a period of ten to fifteen years without replanting, rotation, or fertilization. This exposes the soil to a long drain on its resources. Besides having lasting fertility, the soil should also be of medium consistency so as to allow the plant to benefit by the constant supply of moisture without the soil becoming oversaturated.

Description of the plant.—The abacá is a perennial plant 5 to 10 meters (164 to 33 feet) high. When mature it consists of a group, or cluster, of from 12 to 30 or more stalks of different stages of development. The stalk is cylindrical, $2\frac{1}{2}$ to 6 meters (8 to 20 feet) long, and is formed by the overlapping of the leaf sheaths. The sheaths grow from the fleshy, central core, which is the real stalk, until the

sheath formation is completed, when the flower bud developes and forms the flowering spike. The flowers are borne in clusters subtended by a large membranous bract. The first few bracts which subtend

the real flowers are larger and more conspicuous than the rest which subtend the false flowers. The latter bracts are so densely laid upon one another as to form a kind of flower cone. This cone is smooth, glossy, and of a color ranging from purple to light

8

The fruit is green, 5 to 6 centimeters (2 to green. $2\frac{1}{2}$ inches) long, $1\frac{1}{2}$ to 2 centimeters (0.59 to 0.78 inches) in diameter, inedible, and filled with black seeds.

To The abacá plant closely resembles the banana. the inexperienced eye, it is rather difficult to distinguish the one from the other. The abacá is ordinarily smaller than the banana and its stalks are, as a rule, more slender than those of the latter. The abacá leaf is darker green, narrower, and more tapering than that of the banana. The petiole (leaf stalk) of the abacá leaf is of a light-green color, while that of the banana is gravish.

Stalk formation .- The abacá stalk consists of a fleshy central core and a number of overlapping sheaths. This core is a continuation of the fleshy part of the rootstock, and, as it grows, sheaths are formed on its sides, chiefly at the base. When the stalk reaches maturity sheath formation stops, but the core keeps growing and forms what is known as the "flower spike." The central core, therefore, is really the flower stalk, and its sheaths are prolongations of the petioles of the leaves. This core diminishes in diameter as it rises in the middle of Its diameter at the base of the stalk the stalk. varies from 15 to 35 centimeters (6 to 14 inches), and at the top it rarely exceeds 5 centimeters (2 inches).

The stalk consists of 12 to 25 sheaths, depending on the variety and the extent of growth. The central sheaths alone are exactly the same length as the stalk. The exterior sheaths rise from the base of the core but do not extend to the top of the stalk, and the interior ones, which extend to the top of the stalk, do not rise from the base but at variable intervals above it.

Fiber extraction.—The abacá plant when mature consists of a group of 12 to 30 stalks. These stalks are in all stages of development, but usually two to

four only can be harvested at the same time. stalk is mature at the time of the appearance of the blossom, or shortly before. As a rule no cutting should commence before the plant is 2 to 3 years old. After the first harvest subsequent cuttings can be made every four or six months.

distinct operations: First, the removal of the ribbonlike fibrous strips from the sheath; and, second, the separation of the individual fibers by pulling these strips under a knife.

in front of him, inserts a small, sharp piece of bone or bamboo into the sheath, separates the fibrous strip and pulls it off in two to four ribbons, varying from 5 to 8 centimeters (2 to 3.14 inches) in width and as long as the sheath itself. When these ribbons have been separated, the remainder of the sheath is removed and thrown away as waste. secutive sheath is thus worked until the central core of the stalk is reached.

Nonconservice of the same time. The stark is mature at the time of the appearance of the blossom, or shortly before. As a rule no cutting should commence before the plant is 2 to 3 years old. After the first harvest subsequent cuttings can be nade every four or six months. The process of fiber extraction consists of two distinct operations : First, the removal of the ribbons is eparation of the individual fibers by pulling, these strips under a knife. The laborer, sitting on the ground with a stalk in front of him, inserts a small, sharp piece of bone or bamboo into the sheath, separates the fibrous strips from the sheath; and, second, the separation of the individual fibers by pulling, these strips under a knife. The laborer, sitting on the ground with a stalk in front of him, inserts a small, sharp piece of bone or bamboo into the sheath, separates the fibrous strip and pulls it off in two to four ribbons, varying from 5 to 8 centimeters (2 to 3.14 inches) in width and as long as the sheath itself. When these ribbons have been separated, the remainder of the sheath is removed and thrown away as waste. Each consecutive sheath is thus worked until the central core of the stalk is reached. When a sufficient quantity of these fiber strips, for jibons, has been collected, they are tied in bundles and carried to the stripping apparatus, which consists of a log set in a horizontal position ½ to 1 meter (1½ to 3 feet) from the ground, on top of which is fastened a level block of smooth, hard wood or bamboo. Over this block is placed a knife about 30 centimeters (16 inches) long. Every strip is passed under the knife twice, the second time to pull the which the operator holds in his grasp during the first pull. This process of drawing under the knife twice, the second time to pull the set stores are cleaned, the fiber is hung over a bandoo pole to dry. The produced in the Philippine Islands is extracted with this simple apparation. or ribbons, has been collected, they are tied in bundles and carried to the stripping apparatus, which consists of a log set in a horizontal position $\frac{1}{2}$ to 1 meter $(1\frac{4}{3}$ to 3 feet) from the ground, on top of which is fastened a level block of smooth, hard wood or bamboo. Over this block is placed a knife about 30 centimeters (12 inches) long with a handle 40 centimeters (16 inches) long. Every strip is passed under the knife twice, the second time to pull the butt end which the operator holds in his grasp during the first pull. knife removes all the pulp, leaving in the hands of the operator a bunch of clean, white fiber. soon as the strips are cleaned, the fiber is hung over a bamboo pole to dry.

(\$43.50 to \$50) per acre. During normal prices the net income will be about P90 (\$45) per acre per annum.

Description and uses of the fiber.—Abacá fiber is very light, strong, and durable. When properly extracted and dried, it is also of a white, shining color.

<text><text><text><text><text><text><text><text>

paratively recent origin. Only the highest grades of abacá are used for this purpose, and Japan is by far the largest buyer of the raw fiber. Some European countries buy these high grades, knotted and twisted into hanks, or rolled on bobbins or spools. About 4 or 5 per cent of the supply of abacá is used for this purpose.

<text><text><text><text> early history of the abacá industry until the present time the production of fiber has increased steadily. Unfortunately, however, this increase in production was not the result of, nor was it accompanied by, any general improvement in the cultivation of the plant or in plantation management. Until a short time ago, and in a large measure even at the present time, the bulk of production is the product of small plantings in which old and crude methods of cultivation and fiber extraction have been used. such conditions, therefore, it is not surprising that for a long time it was the belief that the cultivation and production of abacá was not an industry that could be profitably carried on by the use of systematic and modern methods of agriculture.

have been established in different localities and

management to replace the former wasteful and antiquated practices.

The opportunities for the extension of the abacá industry of the Philippines, not so much in an increase in the area cultivated or an increase in production, but in an increase in the yield of plants and an improvement in the quality of the product, are very promising. Improved methods of culture and fiber extraction will largely increase the production of fiber on some of the land already cultivated, while large areas now covered with forest are in every way suitable for abacá and are available for prospective With but little or no danger from insect planters. pests or plant diseases and with but little or no competition from other countries, abacá is an eminently safe crop and affords one of the most profitable branches of agriculture in the Philippines.

Further information on this subject may be obtained from the director-general of the Philippine Exposition Board, Panama-Pacific Exposition, or by application to the Director of Agriculture. Manila, P. I.
